File-System Structure

- File structure
 - ↳ Logical storage unit
 - ↳ Collection of related information
- File system resides on secondary storage (disks).
- File system organized into layers.
- *File control block* – storage structure consisting of information about a file.

Virtual File Systems

- Virtual File Systems (VFS) provide an object-oriented way of implementing file systems.
- VFS allows the same system call interface (the API) to be used for different types of file systems.
- The API is to the VFS interface, rather than any specific type of file system.

Schematic View of Virtual File System

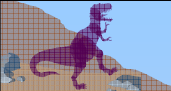

Directory Implementation

- Linear list of file names with pointer to the data blocks.
 - ☞ simple to program
 - ☞ time-consuming to execute
- Hash Table – linear list with hash data structure.
 - ☞ decreases directory search time
 - ☞ *collisions* – situations where two file names hash to the same location
 - ☞ fixed size

Allocation Methods

- An allocation method refers to how disk blocks are allocated for files:
- Contiguous allocation
- Linked allocation
- Indexed allocation

Operating System Concepts 12.10 Silberschatz, Galvin and Gagne ©2002

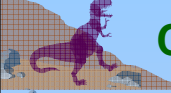

Contiguous Allocation

- Each file occupies a set of contiguous blocks on the disk.
- Simple – only starting location (block #) and length (number of blocks) are required.
- Random access.
- Wasteful of space (dynamic storage-allocation problem).
- Files cannot grow.

Extent-Based Systems

- Many newer file systems (I.e. Veritas File System) use a modified contiguous allocation scheme.
- Extent-based file systems allocate disk blocks in **extents**.
- An **extent** is a contiguous block of disks. Extents are allocated for file allocation. A file consists of one or more extents.

Operating System Concepts 12.13 Silberschatz, Galvin and Gagne ©2002

Linked Allocation

- Each file is a linked list of disk blocks: blocks may be scattered anywhere on the disk.

Linked Allocation (Cont.)

- Simple – need only starting address
- Free-space management system – no waste of space
- No random access
- Mapping

LA/511 Q
R

Block to be accessed is the Qth block in the linked chain of blocks representing the file.
 Displacement into block = $R + 1$

File-allocation table (FAT) – disk-space allocation used by MS-DOS and OS/2.

Example of Indexed Allocation

Indexed Allocation (Cont.)

- Need index table
- Random access
- Dynamic access without external fragmentation, but have overhead of index block.
- Mapping from logical to physical in a file of maximum size of 256K words and block size of 512 words. We need only 1 block for index table.

$$LA/512 \begin{matrix} Q \\ R \end{matrix}$$

Q = displacement into index table
R = displacement into block

Indexed Allocation – Mapping (Cont.)

- Mapping from logical to physical in a file of unbounded length (block size of 512 words).
- Linked scheme – Link blocks of index table (no limit on size).

Q_1 = block of index table

R_1 is used as follows:

Q_2 = displacement into block of index table

R_2 displacement into block of file:

Indexed Allocation – Mapping (Cont.)

- Two-level index (maximum file size is 512^3)

Q_1 = displacement into outer-index

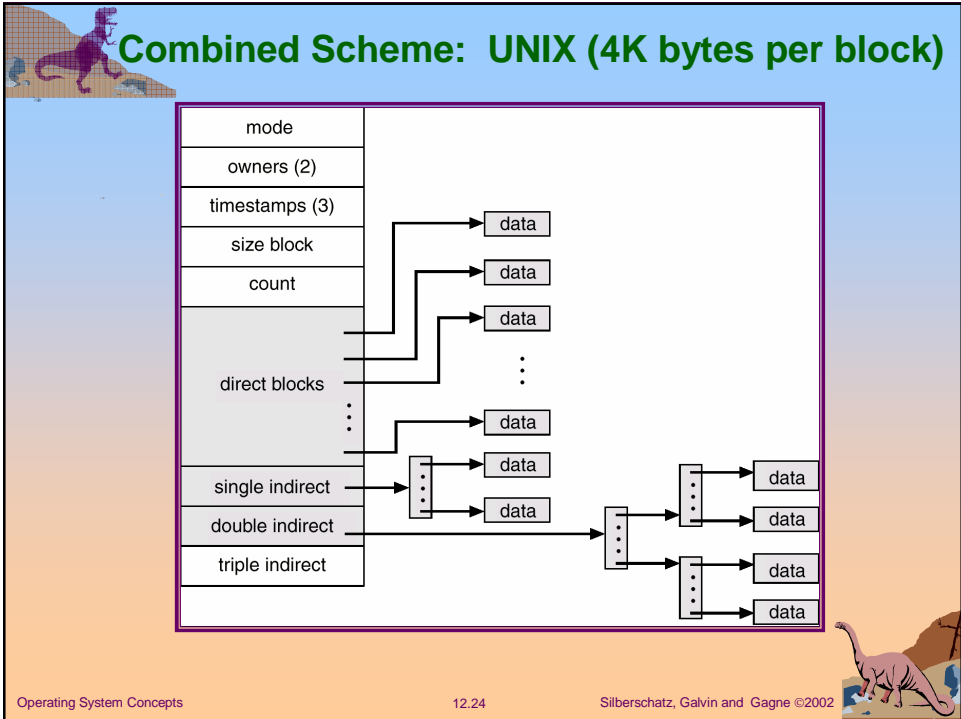

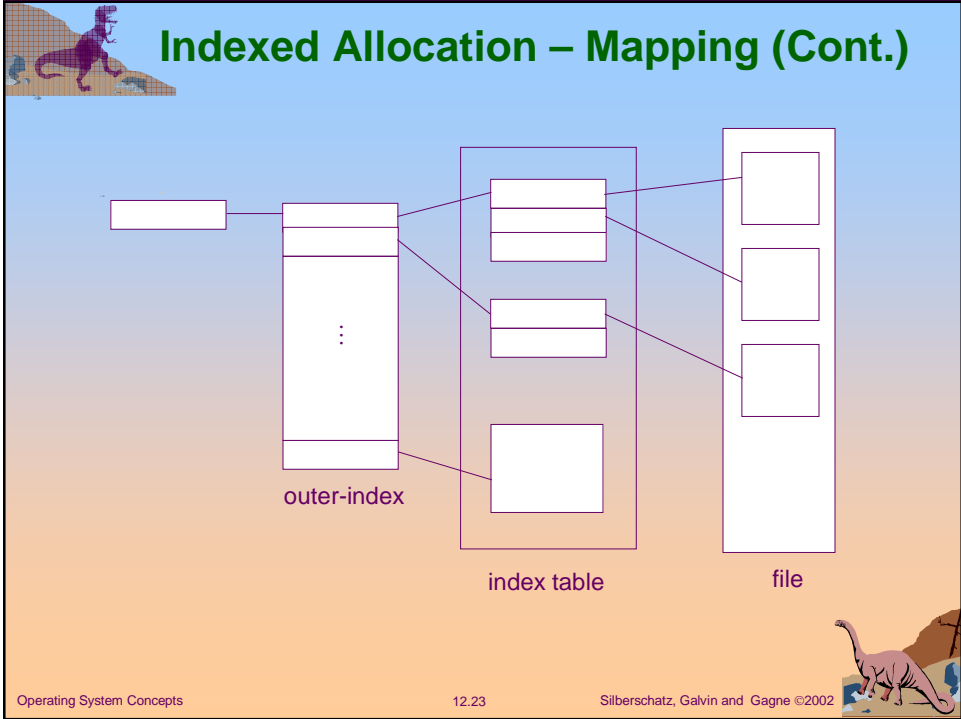

R_1 is used as follows:

Q_2 = displacement into block of index table

R_2 displacement into block of file:

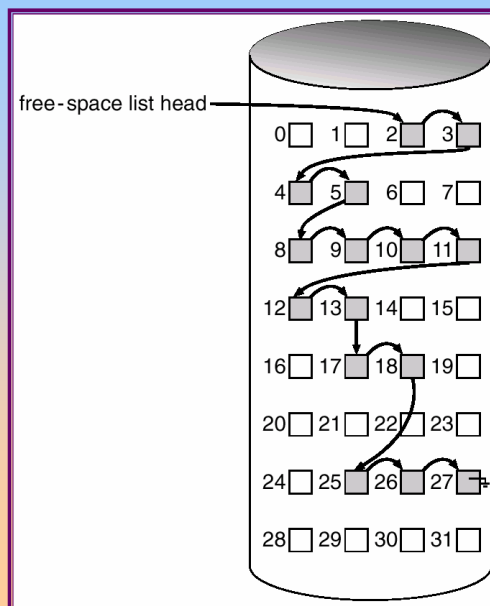

Free-Space Management (Cont.)

- Need to protect:
 - Pointer to free list
 - Bit map
 - ▢ Must be kept on disk
 - ▢ Copy in memory and disk may differ.
 - ▢ Cannot allow for block[*j*] to have a situation where bit[*j*] = 1 in memory and bit[*j*] = 0 on disk.
 - Solution:
 - ▢ Set bit[*j*] = 1 in disk.
 - ▢ Allocate block[*j*]
 - ▢ Set bit[*j*] = 1 in memory

Linked Free Space List on Disk

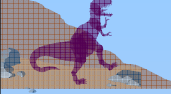

Efficiency and Performance

- Efficiency dependent on:
 - ☞ disk allocation and directory algorithms
 - ☞ types of data kept in file's directory entry
- Performance
 - ☞ disk cache – separate section of main memory for frequently used blocks
 - ☞ free-behind and read-ahead – techniques to optimize sequential access
 - ☞ improve PC performance by dedicating section of memory as virtual disk, or RAM disk.

Various Disk-Caching Locations

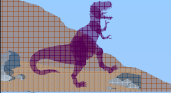

Recovery

- Consistency checking – compares data in directory structure with data blocks on disk, and tries to fix inconsistencies.
- Use system programs to *back up* data from disk to another storage device (floppy disk, magnetic tape).
- Recover lost file or disk by *restoring* data from backup.

Operating System Concepts 12.31 Silberschatz, Galvin and Gagne ©2002

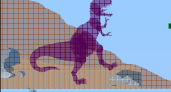

Log Structured File Systems

- **Log structured** (or journaling) file systems record each update to the file system as a **transaction**.
- All transactions are written to a **log**. A transaction is considered **committed** once it is written to the log. However, the file system may not yet be updated.
- The transactions in the log are asynchronously written to the file system. When the file system is modified, the transaction is removed from the log.
- If the file system crashes, all remaining transactions in the log must still be performed.

The Sun Network File System (NFS)

- An implementation and a specification of a software system for accessing remote files across LANs (or WANs).
- The implementation is part of the Solaris and SunOS operating systems running on Sun workstations using an unreliable datagram protocol (UDP/IP protocol and Ethernet).

Operating System Concepts 12.33 Silberschatz, Galvin and Gagne ©2002

NFS (Cont.)

- Interconnected workstations viewed as a set of independent machines with independent file systems, which allows sharing among these file systems in a transparent manner.
 - A remote directory is mounted over a local file system directory. The mounted directory looks like an integral subtree of the local file system, replacing the subtree descending from the local directory.
 - Specification of the remote directory for the mount operation is nontransparent; the host name of the remote directory has to be provided. Files in the remote directory can then be accessed in a transparent manner.
 - Subject to access-rights accreditation, potentially any file system (or directory within a file system), can be mounted remotely on top of any local directory.

Operating System Concepts 12.34 Silberschatz, Galvin and Gagne ©2002

NFS (Cont.)

- NFS is designed to operate in a heterogeneous environment of different machines, operating systems, and network architectures; the NFS specifications independent of these media.
- This independence is achieved through the use of RPC primitives built on top of an External Data Representation (XDR) protocol used between two implementation-independent interfaces.
- The NFS specification distinguishes between the services provided by a mount mechanism and the actual remote-file-access services.

Three Independent File Systems

Mounting in NFS

Mounts

Cascading mounts

NFS Mount Protocol

- Establishes initial logical connection between server and client.
- Mount operation includes name of remote directory to be mounted and name of server machine storing it.
 - Mount request is mapped to corresponding RPC and forwarded to mount server running on server machine.
 - *Export list* – specifies local file systems that server exports for mounting, along with names of machines that are permitted to mount them.
- Following a mount request that conforms to its export list, the server returns a *file handle*—a key for further accesses.
- File handle – a file-system identifier, and an inode number to identify the mounted directory within the exported file system.
- The mount operation changes only the user's view and does not affect the server side.

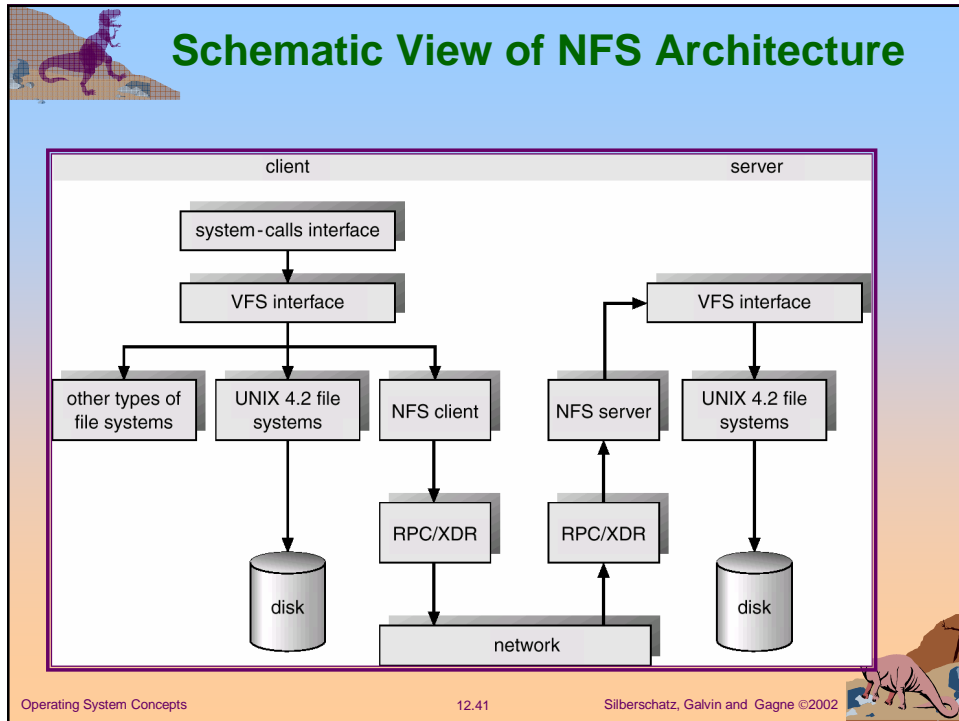

NFS Protocol

- Provides a set of remote procedure calls for remote file operations. The procedures support the following operations:
 - searching for a file within a directory
 - reading a set of directory entries
 - manipulating links and directories
 - accessing file attributes
 - reading and writing files
- NFS servers are *stateless*; each request has to provide a full set of arguments.
- Modified data must be committed to the server's disk before results are returned to the client (lose advantages of caching).
- The NFS protocol does not provide concurrency-control mechanisms.

Three Major Layers of NFS Architecture

- UNIX file-system interface (based on the **open**, **read**, **write**, and **close** calls, and file descriptors).
- *Virtual File System (VFS)* layer – distinguishes local files from remote ones, and local files are further distinguished according to their file-system types.
 - The VFS activates file-system-specific operations to handle local requests according to their file-system types.
 - Calls the NFS protocol procedures for remote requests.
- NFS service layer – bottom layer of the architecture; implements the NFS protocol.

- ## NFS Path-Name Translation
- Performed by breaking the path into component names and performing a separate NFS lookup call for every pair of component name and directory vnode.
 - To make lookup faster, a directory name lookup cache on the client's side holds the vnodes for remote directory names.
- Operating System Concepts 12.42 Silberschatz, Galvin and Gagne ©2002

NFS Remote Operations

- Nearly one-to-one correspondence between regular UNIX system calls and the NFS protocol RPCs (except opening and closing files).
- NFS adheres to the remote-service paradigm, but employs buffering and caching techniques for the sake of performance.
- File-blocks cache – when a file is opened, the kernel checks with the remote server whether to fetch or revalidate the cached attributes. Cached file blocks are used only if the corresponding cached attributes are up to date.
- File-attribute cache – the attribute cache is updated whenever new attributes arrive from the server.
- Clients do not free delayed-write blocks until the server confirms that the data have been written to disk.
